

Die nuts for external threads

The die nuts are threading tools, still widely used, although their use is limited to small series productions.

There are other systems, more modern, more efficient and cheaper to make external threads.

However there are applications where the die nut remains the cheapest tool, such as for example, the threads of individual parts for maintenance, the threads of pipes, for hydraulic installations etc.

This tool has the essential advantage to make a very precise thread.

The die nuts can be classified into two main types: *closed die nuts* and *open die nuts*.

The first rigid die nuts do not allow for any adjustment, because they are constructed from a continuous circular ring, which is why they are preferable in the production of parts that must all be equal (interchangeable).

The open die nuts instead have a radial cut that interrupts the ring and makes elastic the complex (see figure N°1).

This flexibility allows an adjustment of the diameter through which you can get the thread with the desired size.

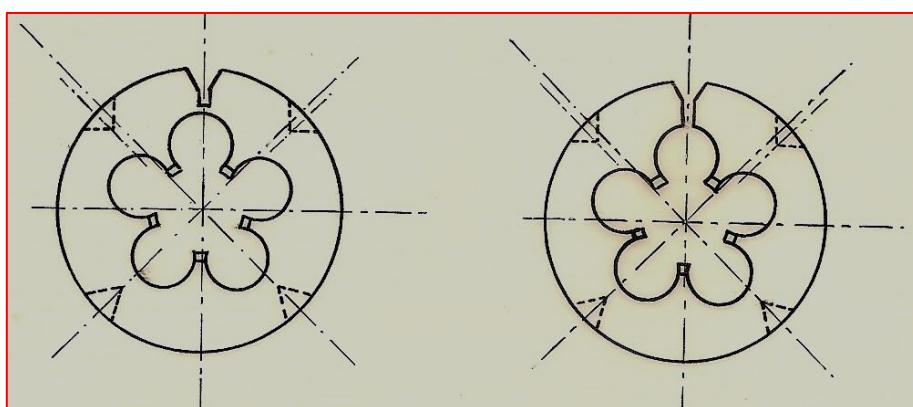

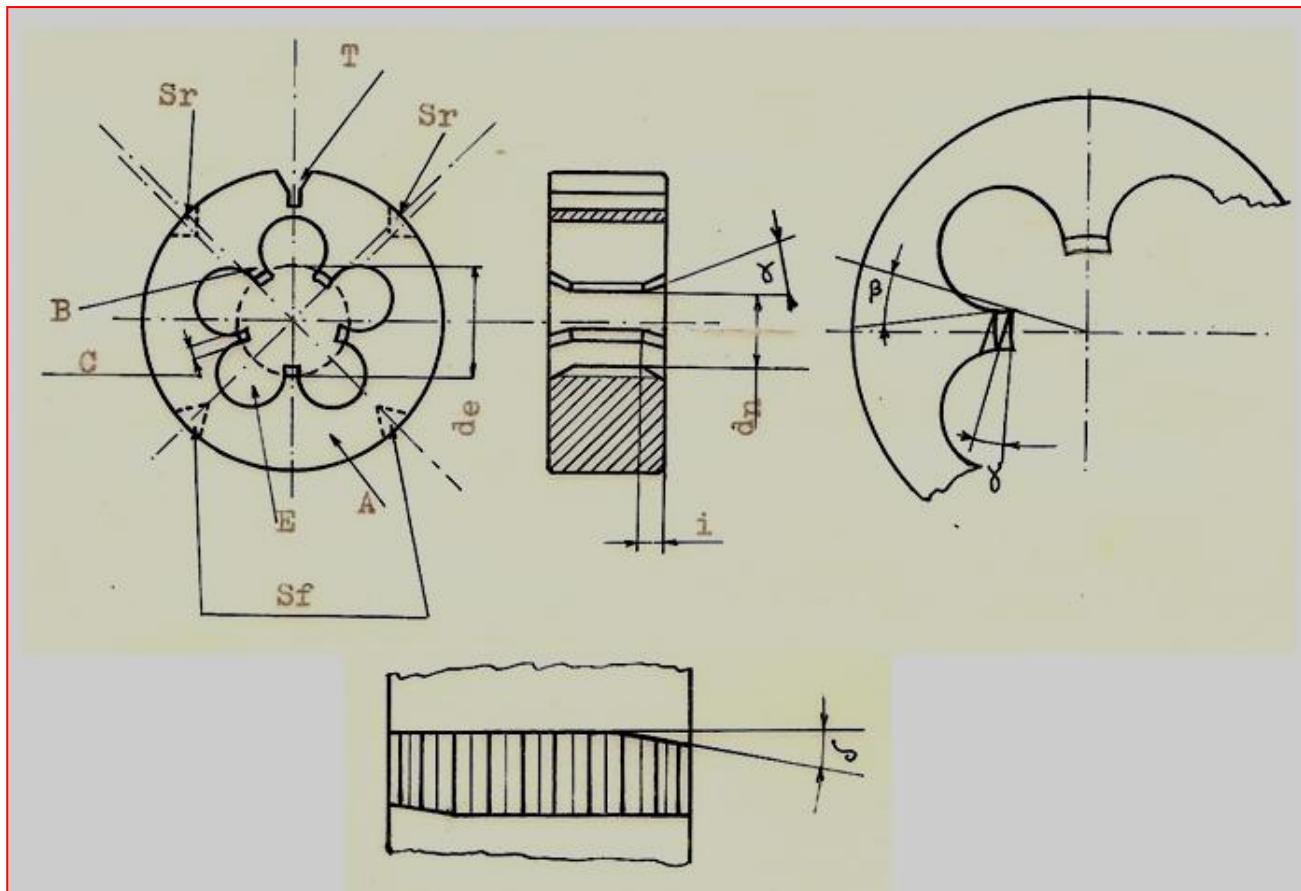

Fig. N°1 – Two types of die nuts

The adjustment must be done with care, however, in the sense that it must go not too far from the final size of the nominal diameter, otherwise you can cause pitch errors, and the surfaces are not well finished.

Fig. N°2- Round die nuts

Figure N°3 summarizes the names of various parts of the round die nuts .

A	Body	d_m	Medium diameter of the thread
B	Tooth or cutting edge	d_n	Root diameter of the thread
C	Width of the cutting edge	i	Length of chamfer
E	Room for chips	p	Pitch
S _f	Conical countersinks for blocking	α	Angle of the chamfer
S _r	Conical countersinks for adjustment	β	Frontal rake angle
T	Preliminary notch for cut of adjustment	γ	Relief angle of the chamfer
d_e	Outside diameter of the thread	δ	Angle of the edge of the chamfer

Fig. N°3- Nomenclature of the part of die nuts

Diameter of the blank

Generally the diameter of the blank is equal to:

$$d_p = d_e - (0,1 \sim 0,2) \cdot p$$

The rake angles, cutting speeds and lubricants suitable for different processes indicated in the table below are indicative. They are bound to different operating conditions, the precise characteristics of the processed material, etc..

Machined material	Rake angle β	Cutting speed m/min	Lubricant
Aluminum and light alloys	20° - 25°	5	Petrolio – O.E.
Duraluminum	15° - 20°	4,5	Rapeseed oil– O.E.
Brass	3° - 5°	10	O.E.
Bronze	5° - 8°	6	Rapeseed oil
Copper	15° - 20°	6	Rapeseed oil– O.E.
Cast iron	5° - 8°	3,5	O.E.
Steel R < 750 N/mm ²	12° - 18°	2,5	Oil sulfide– O.E.
Steel R > 750 N/mm ²	10° - 12°	2	Idem
Hard steels	8° - 10°	4,5	Idem
Bakelite	3°	3	Dry with air jet

The angle of the chamfer is almost always 30° and the rake angle of chamfer is 6° . The modification of the chamfer is applied primarily on dies for machining operations because it causes the expulsion of the chips in the sense of the feed and avoid clogging in the rooms.

The angle δ varies from 8° for machining of steel at 12° for machining of light alloys. With reference to figure N°4, the size of the dies, according to the standards DIN EN 22 568, and DIN-EN 24 231 are shown in the tables below (taken from the catalog Vergnano).
